Heats of Combustion and Isomerization of the Six C7H14 Alkylcyclopentanes

By Walter H. Johnson, Edward J. Prosen, and Frederick D. Rossini

The heats of isomerization of the six C7H14 alkylcyclopentanes were determined by measurement of the ratios of the heats of combustion of purified samples of these compounds in the liquid state by the procedure previously described for other isomeric hydrocarbons. The data yield the following values for the heat of isomerization, ΔH°, in the liquid state at 25° C, of ethylcyclopentane into each of the dimethylecyclopentanes, in kilocalories per mole: Ethylcyclopentane, 0.00; 1,1-dimethylecyclopentane, -2.06 ± 0.12; cis-1,2-dimethylecyclopentane, -0.44 ± 0.20; trans-1,2-dimethylecyclopentane, -1.86 ± 0.16; cis-1,3-dimethylecyclopentane, -1.11 ± 0.24; trans-1,3-dimethylecyclopentane, -1.60 ± 0.14. These values were combined with values for the differences in the heats of vaporization of these isomers to obtain values for the heats of isomerization in the gaseous state at 25° C.

Utilizing the values previously reported for the heats of combustion and formation of ethylcyclopentane in the liquid and gaseous states at 25° C, values were calculated for the heats of combustion and formation of the five dimethylecyclopentanes in the liquid and gaseous states at 25° C.

I. Introduction

In continuation of the program of determining the heats of combustion, formation, and isomerization of hydrocarbons of various types [1],1 calorimetric measurements have been made that yield values for the differences in the heats of combustion, or the heats of isomerization, of the six C7H14 alkylcyclopentanes in the liquid state at 25° C. These values of heats of isomerization were combined with values [2] for the differences in the heats of vaporization of these isomers at 25° C to obtain values for the heats of isomerization in the gaseous state at 25° C. Utilizing the values previously reported [3] for the heats of combustion and formation of ethylcyclopentane in the liquid and gaseous states at 25° C, corresponding values were calculated for the five dimethylecyclopentanes.

II. Unit of Energy, Molecular Weights, Uncertainties

The unit of energy upon which values reported in this paper are based is the absolute joule, derived from mean solar seconds and absolute ohms and volts, in terms of which certification of standard resistors and cells is made by this Bureau. For conversion to the conventional thermochemical calorie, the following relation is used [4, 5]:

1 calorie = 4.1840 absolute joules.

The molecular weight of carbon dioxide, the mass of which was used to determine the amount of reaction, was taken as 44.010, from the 1947 table of international atomic weights [6].

The uncertainties assigned to the various quantities dealt with in this paper were derived, where possible, by a method previously described [7].
Definitions of the symbols used are given in previous papers [1, 8].

III. Method and Apparatus

The same method and apparatus were used as in the investigations recently reported from this laboratory [1]. One calorimetric system, resistance bridge (No. 404), and platinum resistance thermometer (No. 373,730) were used for all the experiments reported here.

No products associated with incomplete combustion were found in any of the experiments.

IV. Materials

The compounds used in the present investigation were samples from the API-NBS series of highly purified hydrocarbons, which are being prepared through a cooperative undertaking of the American Petroleum Institute and the National Bureau of Standards.

These samples of API-NBS hydrocarbons have been made available by the American Petroleum Institute and the National Bureau of Standards through the API Research Project 44 on the "Collection, analysis, calculation, and compilation of data on the properties of hydrocarbons." The samples were purified at the National Bureau of Standards by the API Research Project 6 on the "Analysis, purification, and properties of hydrocarbons," from material supplied by the following laboratories:

Ethylcyclopentane (A), cis-1,3-dimethylcyclopentane, and trans-1,3-dimethylcyclopentane (A) by the American Petroleum Institute Research Project 45 at the Ohio State University, Columbus, Ohio, under the supervision of C. E. Boord.

1,1-Dimethylcyclopentane, cis-1,2-dimethylcyclopentane, and trans-1,2-dimethylcyclopentane by Hydrocarbon Laboratory at the Pennsylvania State College, State College, Pa.

A complete description of the purification, purity, and freezing points of the six API-NBS hydrocarbons used in the present investigation is given in references [9, 10, 11], which reported the amounts of impurity in these samples, as determined from measurements of freezing points, to be as follows in mole fraction: Ethylcyclopen-
tane (A), 0.0008 ± 0.0004; 1,1-dimethylcyclopentane, 0.0003 ± 0.0002; cis-1,2-dimethylcyclopentane, 0.00025 ± 0.00016; trans-1,2-dimethylcyclopentane, 0.0013 ± 0.0010; cis-1,3-dimethylcyclopentane, 0.0041 ± 0.0023; trans-1,3-dimethylcyclopentane (A) 0.0035 ± 0.0009.

As the manner of purification [9, 10, 11] was such as to leave substantially only close-boiling isomeric impurities in the respective compounds, it is calculated that in the extreme case the measured heat of combustion would be affected by less than 0.001 percent because of impurities.

The samples of trans-1,2-dimethylcyclopentane and trans-1,3-dimethylcyclopentane are the racemic mixtures of the dextro and levo forms. With regard to energy content, the dextro and levo forms are identical, and any difference between these and the racemic mixture would be insignificant.

V. Results

The experimental results of the present investigation are summarized in table 1, which gives for each of the six compounds the following data: The number of experiments performed; the minimum and maximum values of the mass of carbon dioxide formed in the combustion and of the calorimetric quantities, \( \Delta R_t \), \( \Delta r_t \), and \( \Delta r_n \) [8]; the mean value of \( B \), and its standard deviation, in ohms per gram of carbon dioxide formed, as defined by eq 4 of reference [8]. The symbols have the same significance as in reference [1].

In table 2 are given, for the six \( \text{C}_7\text{H}_{14} \) alkylcyclopentanes, values of the following: The constant \( B \), in ohms per gram of carbon dioxide, as given in table 1; \( B^0 \), which is the value of \( B \) corrected to the ideal bomb reaction by the method of Washburn [12]; \( B^e/B^0 \), which is equal to the ratio of the heat evolved, per mole of hydrocarbon, in the ideal bomb process at 28\( ^\circ \)C for each isomer to that of ethylcyclopentane; and \( (-\Delta U^0)_n-(-\Delta U^0)_i \), the difference, between ethylcyclopentane and each isomer, in the heat of combustion in the ideal bomb process at 28\( ^\circ \)C.

\[ \text{The Washburn correction is the same for all these compounds as they are isomers, but account is taken of the variation of the correction with the amount of sample burned. As used here, the Washburn correction was modified to apply to 28\( ^\circ \)C (the temperature to which the measured heat of combustion is referred) and to the gases at zero pressure (instead of 1 atmosphere).} \]

The values of the differences in the heats of combustion in the ideal bomb process, $(-\Delta U^0)_n - (-\Delta U^0)_i$, were obtained by means of the relation [8]

$$(-\Delta U^0)_n - (-\Delta U^0)_i = (-\Delta U^0)_n \left(1 - B_i/B_n\right).$$

For this calculation, the value of $(-\Delta U^0)_n$ at 28°C was taken from reference [13] as 4581.5 int kJ/mole or 4582.3 abs kJ/mole.

In table 3 are given, for the six C₇H₁₄ alkylcyclopentanes, values for the following: $H_i - H_n$, the heat of isomerization of ethylcyclopentane into each isomer at 25°C for the liquid and gaseous states; $-\Delta H^c$, the decrement in the heat content accompanying the reaction of combustion of the hydrocarbon in the liquid or gaseous state, as indicated, in gaseous oxygen to form gaseous carbon dioxide and liquid water at 25°C; and $\Delta H^f$, the increment in heat content or enthalpy of the process of forming the given hydrocarbon in the liquid or gaseous state, as indicated, from its elements, gaseous hydrogen and solid carbon (graphite), at 25°C.

</table>

The heat of isomerization, \( H^o_i - H^o_n \), in the liquid state at 25°C was taken as equal to the difference \(( -\Delta U^o)_i - (-\Delta U^o)_n \) between each isomer and ethylcyclopentane, in the heats of combustion in the ideal bomb process at 28°C, since for these isomers the conversion to the constant-pressure process and to 25°C will be the same, well within the limits of uncertainty assigned to the values.

The heats of isomerization, \( H^o_i - H^o_n \), in the gaseous state, were obtained from the values in the course of the heat of isomerization of any one of the isomers into that of ethylcyclopentane [2], in kcal/mole: Ethylcyclopentane, 0.00; 1,1-dimethylcyclopentane, 0.64; cis-1,2-dimethylcyclopentane, 0.17; trans-1,2-dimethylcyclopentane, 0.46; cis-1,3-dimethylcyclopentane, 0.47; trans-1,3-dimethylcyclopentane, 0.52.

The value of the heat of combustion or formation of a given isomer was obtained by appropriately combining the heat of isomerization with the heat of combustion or formation of ethylcyclopentane as given by the following values from references [13, 14, 15]:

\[ C_7H_{14}(\text{ethylcyclopentane, liquid}) + 21/2O_2(gas) = 7CO_2(gas) + 7H_2O(liquid). \]

\[ \Delta H^o_{298,16} = -1097.50 \pm 0.22 \text{ kcal/mole}. \]

\[ C_7H_{14}(\text{ethylcyclopentane, gas}) + 21/2O_2(gas) = 7CO_2(gas) + 7H_2O(liquid). \]

\[ \Delta H^o_{298,16} = -1106.23 \pm 0.23 \text{ kcal/mole}. \]

\[ 7C(\text{solid, graphite}) + 7H_2(gas) = C_7H_{14}(\text{ethylcyclopentane, liquid}). \]

\[ \Delta H^o_{298,16} = -39.08 \pm 0.24 \text{ kcal/mole}. \]

\[ 7C(\text{solid, graphite}) + 7H_2(gas) = C_7H_{14}(\text{ethylcyclopentane, gas}). \]

\[ \Delta H^o_{298,16} = -30.35 \pm 0.25 \text{ kcal/mole}. \]

All the uncertainties assigned to the experimental quantities in table 2 (except the heats of combustion and formation) are equal to twice the standard deviation of the mean. The uncertainties assigned to the values of the heats of combustion and formation were obtained by combining [7] the uncertainty in the values of the heats of combustion and formation of ethylcyclopentane [14], with the uncertainties in the values of the heats of isomerization. The uncertainty to be assigned to the value of the heat of isomerization of any one of the isomers into any other one may conservatively be taken as ±0.25 kcal/mole.
