PHASE EQUILIBRIA IN THE SYSTEM Cr$_2$O$_3$-Al$_2$O$_3$

By E. N. Bunting

ABSTRACT
A study of the phase equilibria in the Cr$_2$O$_3$-Al$_2$O$_3$ system has shown these oxides to be completely miscible in the liquid and solid states, with no compound formation. The melting point of Cr$_2$O$_3$ has been redetermined to be 2,275° ± 25° C.

I. INTRODUCTION
A dilute solution of Cr$_2$O$_3$ in Al$_2$O$_3$ has long been known as the ruby. More concentrated solutions do not possess the desirable color of the ruby, but are of interest because of their refractory properties.

Duboin$^1$ reported that on heating mixtures of Cr$_2$O$_3$ and Al$_2$O$_3$ to a “red white” heat, from 15 to 16 per cent Cr$_2$O$_3$ united with the Al$_2$O$_3$. Passerini$^2$ made an examination by X rays of mixtures which had been heated to 600° C. and found that limited solution in the solid state occurred at this temperature.

II. MATERIALS AND GENERAL PROCEDURE
A homogeneous solution of “C. P.” Cr$_2$(SO$_4$)$_3$·(NH$_4$)$_2$SO$_4$·24H$_2$O and Al$_2$(SO$_4$)$_3$·(NH$_4$)$_2$SO$_4$·24H$_2$O in warm water was treated with an excess of ammonium hydroxide. Since both hydroxides are very insoluble a thoroughly mixed precipitate is obtained in this way and mixtures of known composition could be made from weighed amounts of the salts. The washed and filtered hydroxides were ignited to oxides in a platinum crucible over a Meker burner.

The melting temperatures of these mixtures were determined by means of an iridium button (fig. 1) heated by high frequency induction. A small piece of the material, about one-half millimeter in size, was placed in the central hole and covered with a larger piece of the same mixture to promote uniformity of temperature within the space occupied by the small piece. The

button was heated to a series of temperatures in steps of 10° C., as measured by an optical pyrometer sighted into the smaller of the two holes in the button. After each temperature step the larger piece of material was removed from the cold button and the smaller piece examined with a magnifying glass. An error of 10° or more is possible in judging the condition of partial melting. The calibration of the optical pyrometer was checked before and after these observations were made, and the results are probably accurate within ±25° C.

The temperature of complete fusion was obtained by observing two or three very small pieces of a mixture in the hole as the temperature was raised. Mixtures containing up to 30 mole per cent Cr₂O₃ readily "wet" the iridium on melting, while those with high Cr₂O₃ content did not, so that the temperature of complete melting of the high Cr₂O₃ mixtures could not be determined accurately.

### III. RESULTS

The data obtained are shown in Table 1 and Figure 2. They indicate a continuous series of solid solutions. X-ray spectrograms of mixtures containing 20, 40, and 70 mole per cent Cr₂O₃ and which had been fused are shown in Figure 3. The absence of additional lines in the spectrograms of the mixtures and the progressive shifting of the lines as the Al₂O₃ content is increased demonstrate that no compounds are formed, but that complete miscibility occurs in the solid state.

IV. THE MELTING POINT OF Cr$_2$O$_3$

In a previous paper \(^4\) the melting point of Cr$_2$O$_3$, which had been prefused in an oxyhydrogen flame, was reported to be $2,140^\circ \pm 25^\circ$ C. As there is a possibility of reducing some of the Cr$_2$O$_3$ by prefusion in this manner,\(^5\) a sample of unfused Cr$_2$O$_3$ was prepared from Cr$_2$(SO$_4$)$_3$. (NH$_4$)$_2$SO$_4$.24H$_2$O. The melting point of this unfused Cr$_2$O$_3$ was found to be $2,275^\circ \pm 25^\circ$ C., as determined in the iridium button. The vapor pressure of Cr$_2$O$_3$ at this temperature must be considerably under atmospheric pressure, as small pieces kept at this temperature for several minutes did not evaporate from the hole in the button. Wartenberg and Werth could not obtain the melting point of Cr$_2$O$_3$ in a zirconia furnace, fired with oxygen and atomized oil, because of excessive vaporization above $2,200^\circ$ C., and concluded that Cr$_2$O$_3$ sublimed before reaching its melting point. In the presence of reducing gases, which would diffuse through a zirconia tube at this temperature, the Cr$_2$O$_3$ may have been reduced and vaporized as the metal or a lower oxide, since Cr$_2$O$_3$ is very susceptible to reduction at high temperatures.
